

# Principle of operation of D.C. Machine as a Motor:-

→ when a current carrying conductor is placed in a magnetic field, it experiences a mechanical force.

Conductor in a magnetic field

Flux produced by current carrying conductor.

interaction of two fluxes

Force experienced by the conductor.

## Fleming's left hand rule:-

direction of the force experienced by conductor.

The direction of Rotation of Motor:-

the magnitude of force experienced by the conductor in motor is  $F = B l I$  newtons

$B$  = Flux density due to the flux produced by the field winding

$l$  = A length of the conductor

$I$  = Current passing through the conductor.

The direction of such force i.e the direction of rotation of a motor can be determined by Fleming's left hand rule. So Fleming's right hand rule is to determine direction of induced emf i.e for generating action while Fleming's left hand rule is to determine direction of force experienced i.e for motoring action.

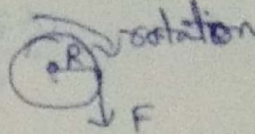

back emf:-

(a) back emf in a d.c motor

## → Torque equation of D.C. Motor:-

It is seen that the turning or twisting force about an axis is called torque. 

Consider a wheel of radius  $R$  meters acted upon the by a circumferential force  $F$  newtons

the wheel is rotating at a speed of  $N$  rpm  
then angular speed of the wheel is

$$\omega = \frac{2\pi N}{60} \text{ rad/sec}$$

So work done in one revolution is

$$W = R \times \text{distance travelled in one revolution (perimeter)}$$

$$W = F \times 2\pi R \text{ joules}$$

$$P = \text{Power developed} = \frac{\text{Work done}}{\text{time}}$$

$$= \frac{F \times 2\pi R}{\text{time for 1 rev}} = \frac{F \times 2\pi R}{\frac{60}{N}}$$

$$= (F \times R) \left( \frac{2\pi N}{60} \right)$$

$$P = T \times \omega \text{ watts}$$

$$T = \text{Torque in N-m}$$

$$\omega = \text{Angular speed in rad/sec}$$

Let  $T_a$  be the gross torque developed by the armature of the motor. It is <sup>also</sup> called armature torque. The gross mechanical power developed in the armature is  $E_b T_a$ .

$$P = T \times \omega$$

$$E_b \omega_a = T_a \times \frac{2\pi N}{60}$$

$$E_b = \frac{\phi Z N P}{60 A}$$

$$\frac{\phi Z N P}{60 A} \times T_a = T_a \times \frac{2\pi N}{60}$$

$$T_a = \frac{1}{2\pi} \phi T_a \frac{P Z}{A}$$

$$\therefore T_a = 0.159 \phi T_a \frac{P Z}{A}$$

$$\frac{0.159 \phi T_a P Z}{A} = 1$$

If both sides are in revolution

W = 2 x distance travelled in one revolution (m/min)

$$W = 2 \pi r \times T = 14$$

$$\frac{\text{distance}}{\text{time}} = \text{speed} = 9$$

$$\frac{2\pi r T}{\frac{60}{s}} = \frac{2\pi r T}{\text{time for 1 rev}} =$$

$$\left(\frac{14}{60}\right) (2\pi r T) =$$

$$P = T \times \omega$$

$$P = T \times \omega$$

W = 2 x distance travelled in one revolution

W = 2 x distance travelled in one revolution

W = 2 x distance travelled in one revolution

W = 2 x distance travelled in one revolution
